who am i?

Human Computer Interaction (HCI)::

a multidisciplinary field of study focusing on the design of computer technology and, in particular, the interaction between humans (the users) and computers

experimental design psychology

experimental psychology::

the branch of psychology concerned with the scientific investigation of the responses of individuals to stimuli in controlled situations

e.g. bandwagon effect (one of our many cognitive biases)

what is the link with statistics?

like in many fields, statistics is the main tool to analyse, demonstrate, evaluate or predict

let's start with an example

imagine you are designing a graphical interface for a new application on a laptop

how big should the buttons/icons be?

Fitts' law ::

the time required to acquire a target of size w at distance d can be described as $T = a + b \log (1 + d/w)$

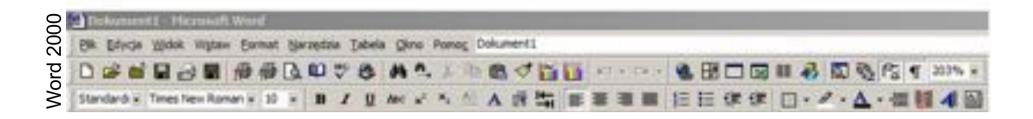

smaller bin = harder and further = harder

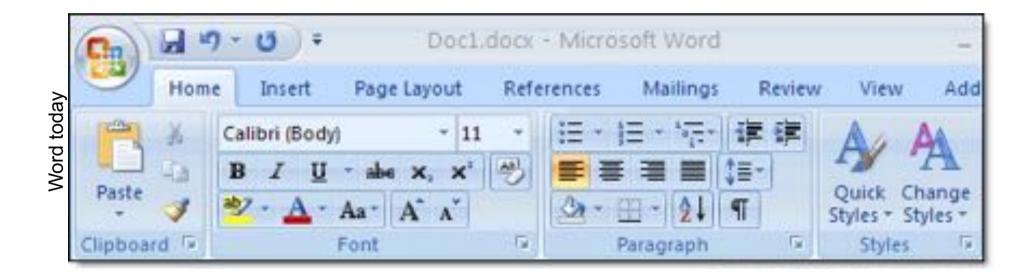

Fitts' law ::

the time required to acquire a target of size w at distance d can be described as $T = a + b \log (1 + d/w)$

$$T = \underbrace{a + b}_{\text{Index}} D_{\text{ifficulty}}$$
(depends on input device)

e.g. one reason why we have ribbons in Word now

Fitts' law :: T = a + b ID

time required to acquire a target

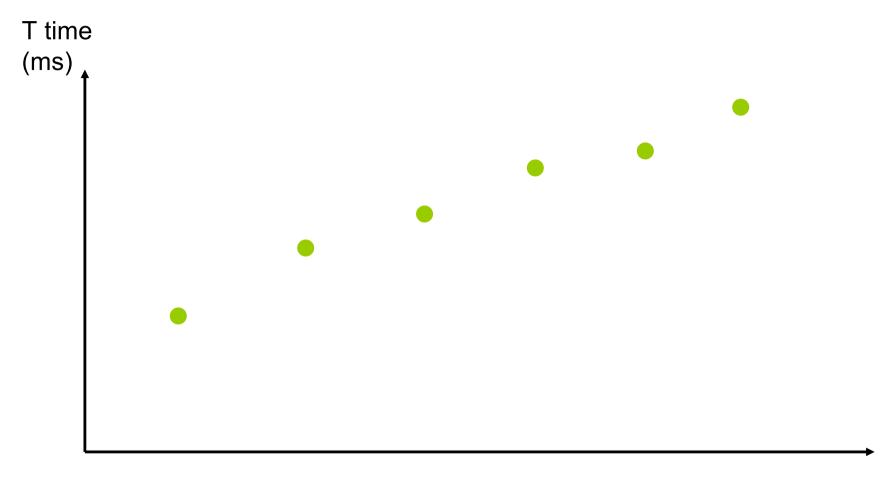

but where does this equation come from?

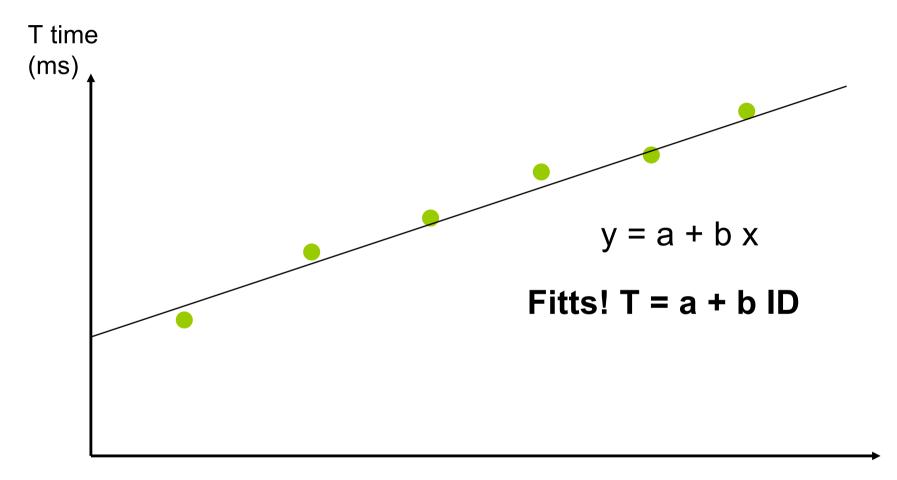

+

let's run an experiment and ask one participant to click on targets of different IDs

ID index of difficulty

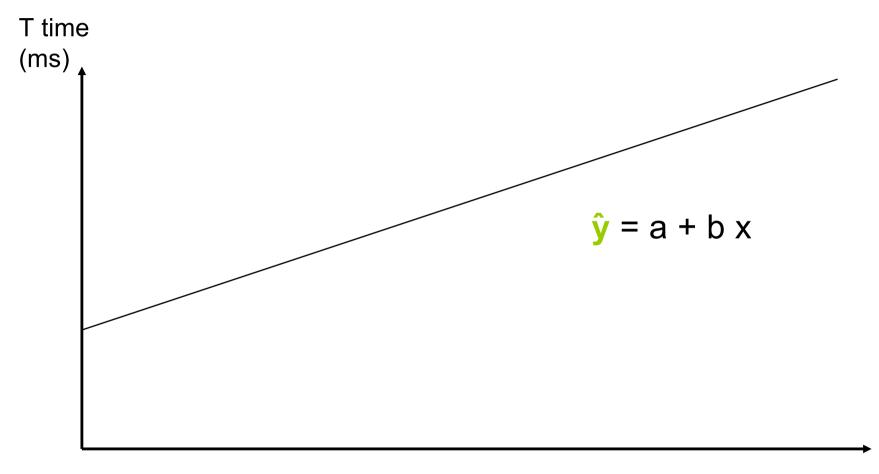

regression ::

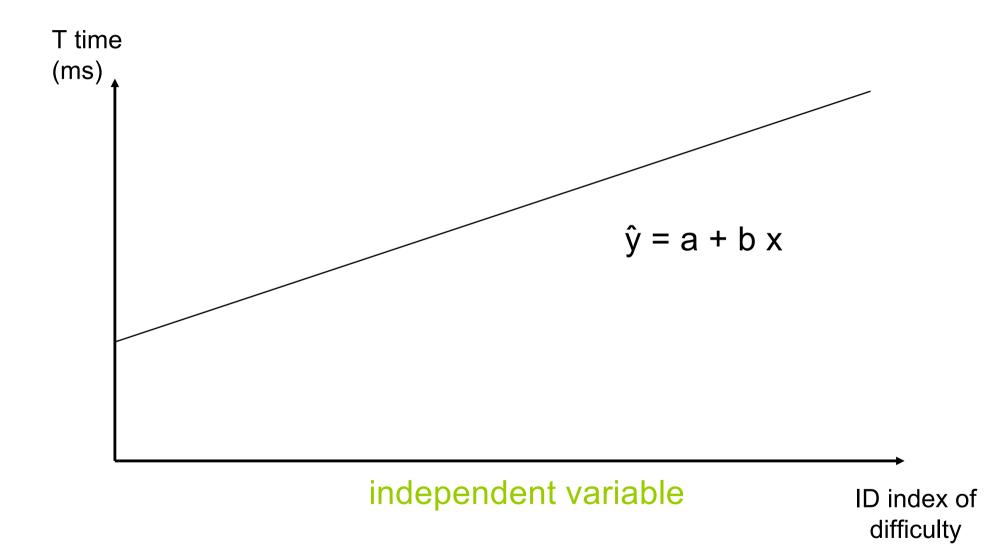

a technique for determining the statistical relationship between two or more variables where a change in a dependent variable is associated with, and depends on, a change in one or more independent variables

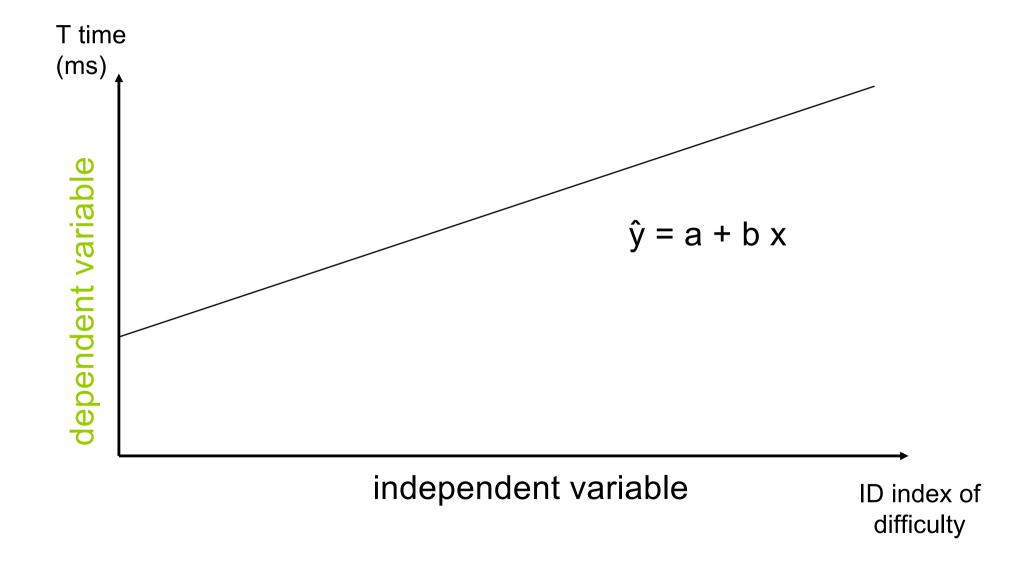

arguably the most basic technique for machine learning

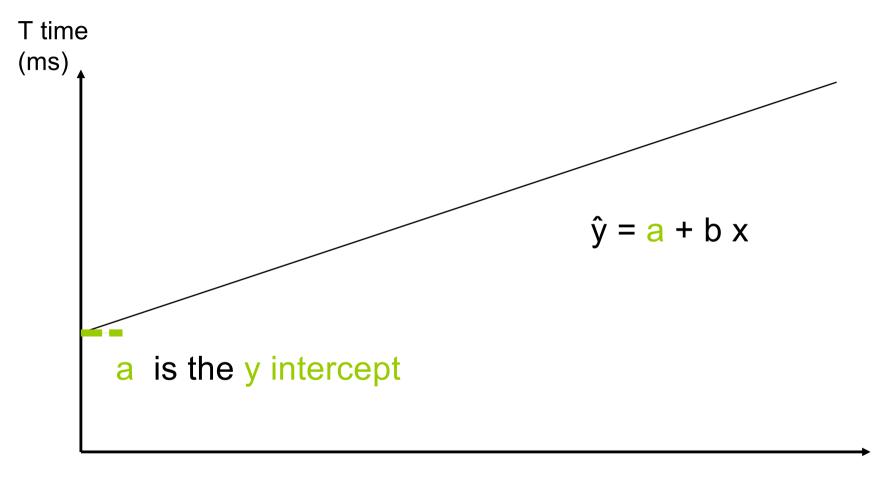

terminology of regressions

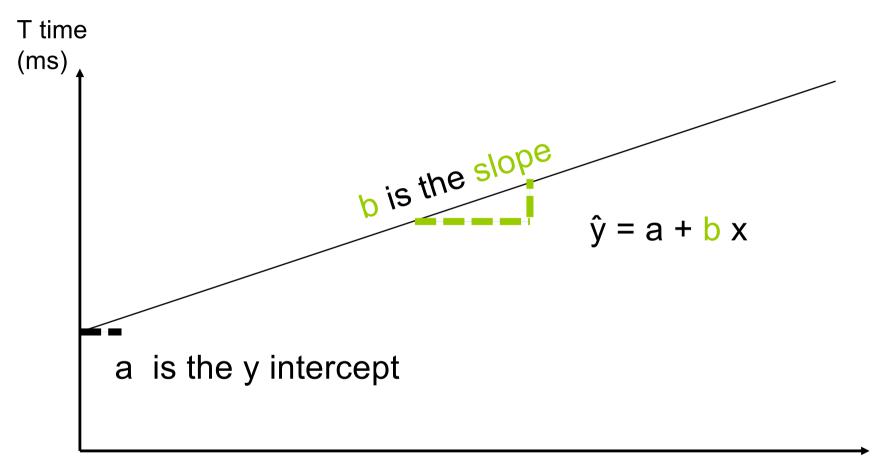

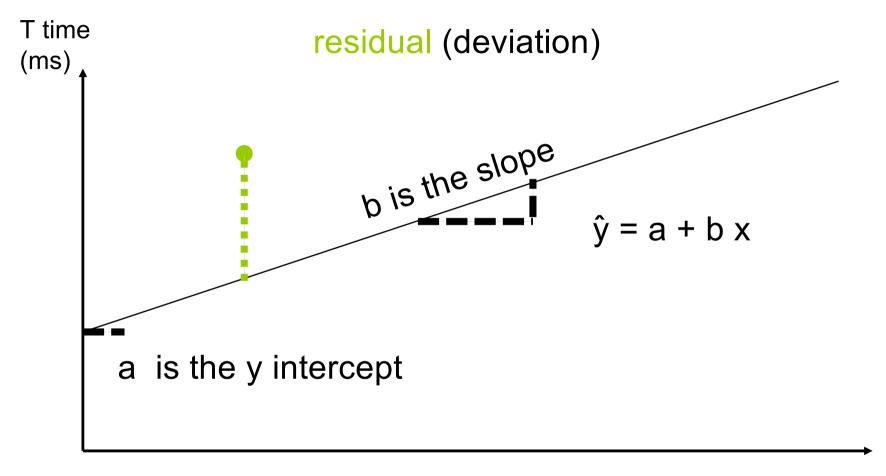

ID index of difficulty

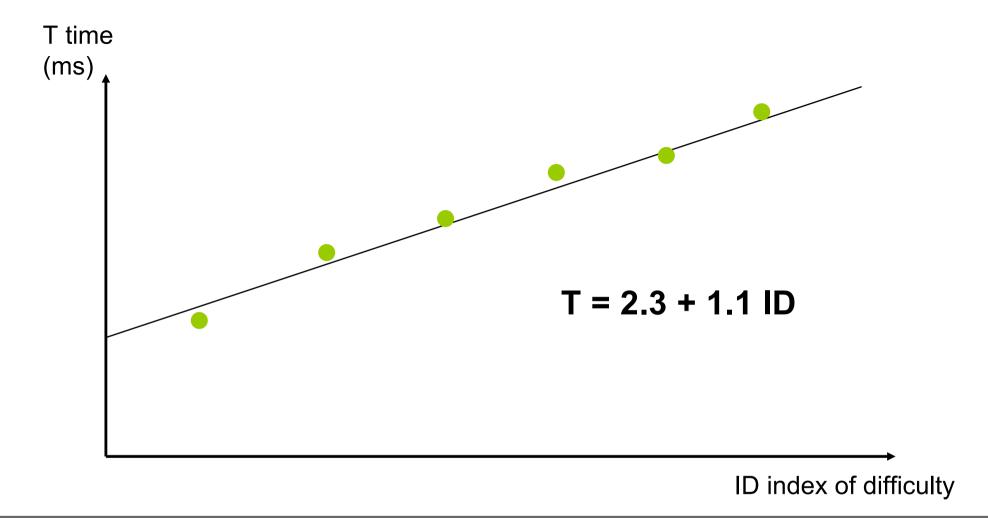

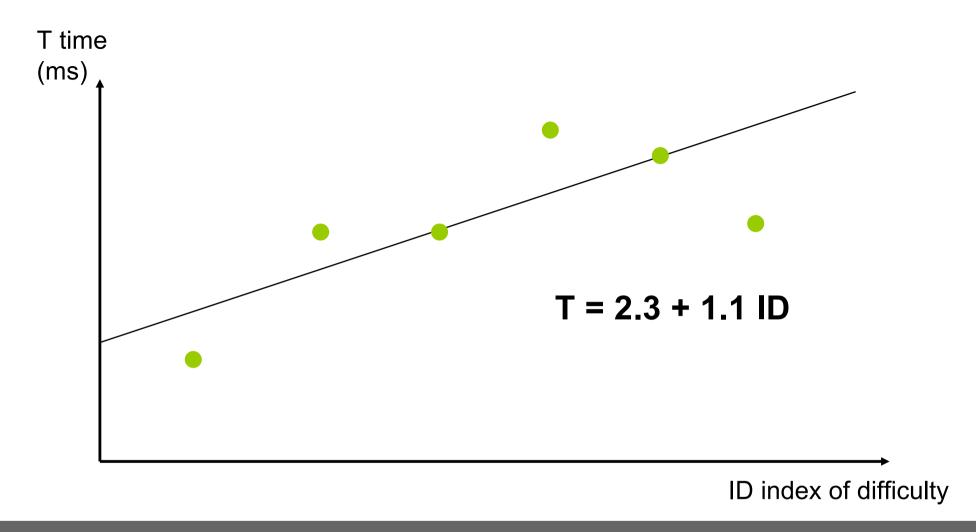

goodness of fit

how can you be sure this line is a good fit to our data?

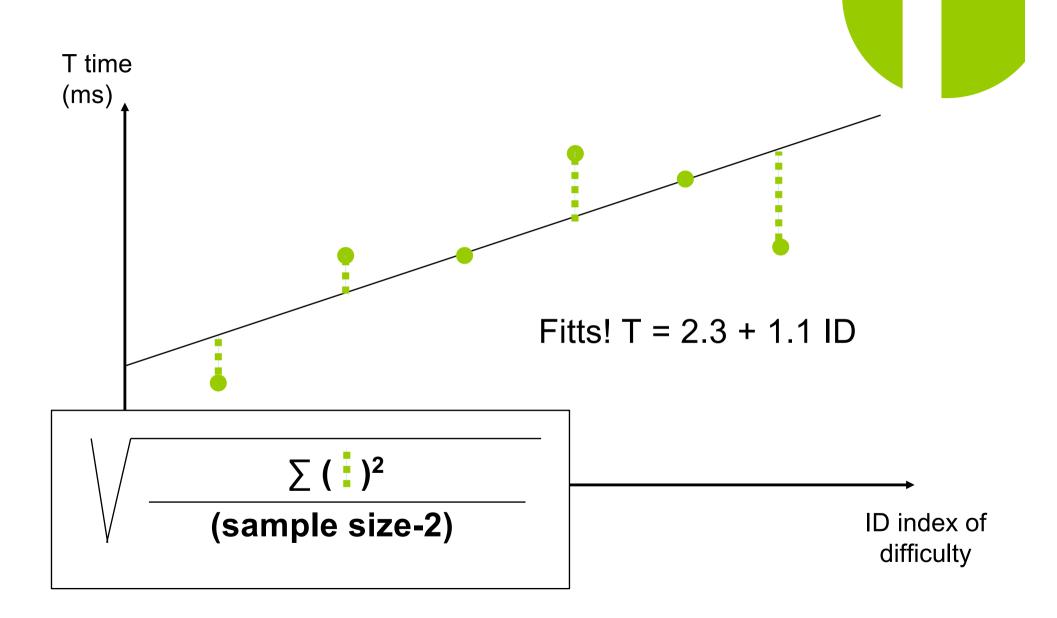

how can you be sure this line is a good fit to our data? what about now?

<brainstorming with your neighbor>

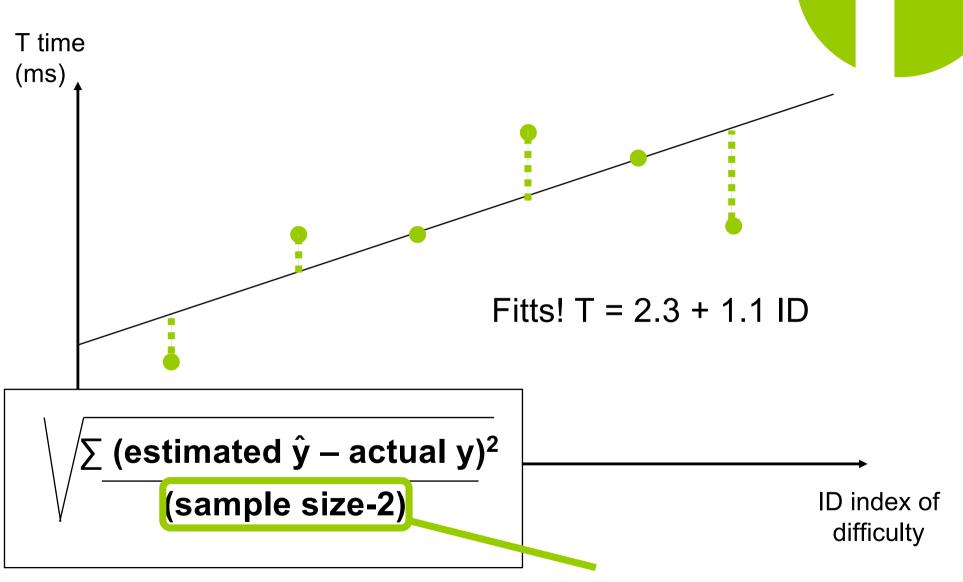

we can compute the goodness of fit with several methods

e.g. standard error of the estimate or R squared

standard error of the estimate

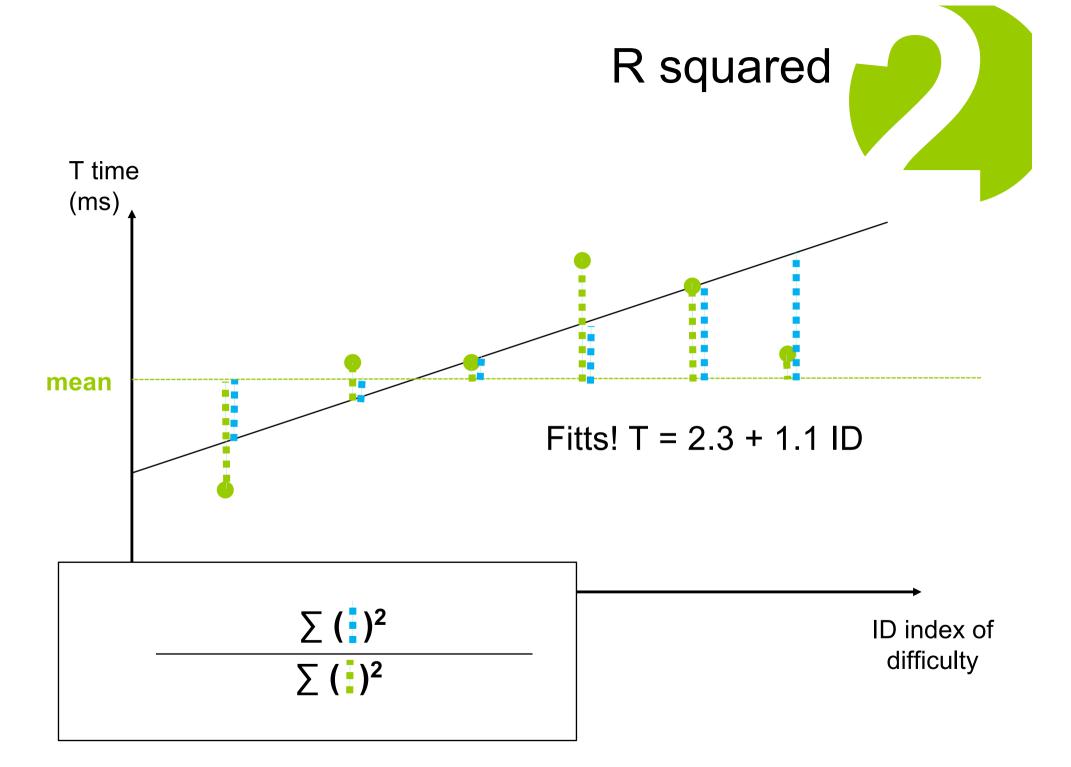

standard error of the estimate

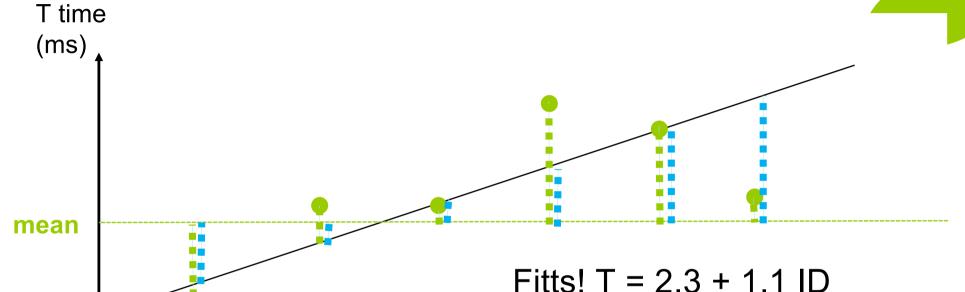

also called degree of freedom

S gives a standard error in the metric of the data (the less the better)

 $\frac{\sum (\text{estimated } \hat{y} - \text{mean } y)^2}{\sum (\text{actual } y - \text{mean } y)^2}$

this formula works if your line is computed by the least square regression method (the one used by R)

R squared

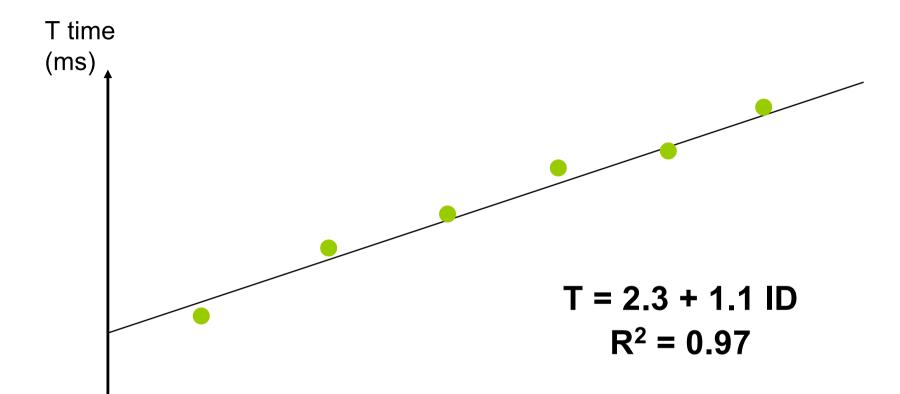

Fitts! T = 2.3 + 1.1 ID

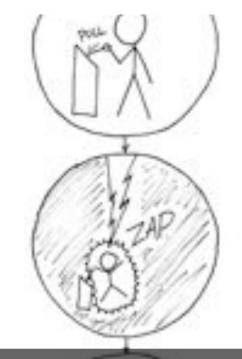

1 -
$$\frac{\sum (actual \ y - estimated \ \hat{y})^2}{\sum (actual \ y - mean \ y)^2}$$

you could also find it in a this format which is more genetic R² gives a percentage and 100% means perfect fit (>70% is better)

how can you be sure this is a good fit for all human?

to gain additional confidence we repeat

we gain trust in a model if it fits the data with little error when

1.it is verified with a lot of data

2.it holds across very different people

3.it is verified in independent studies.

The information capacity of the human motor system in controlling the amplitude of movement.

PM Fitts - Journal of experimental psychology, 1954 - psycnet.apa.org

Reports of 3 experiments testing the hypothesis that the average duration of responses is directly proportional to the minimum average amount of information per response. The results show that the rate of performance is approximately constant over a wide range of movement amplitude and tolerance limits. This supports the thesis that" the performance capacity of the human motor system plus its associated visual and proprioceptive feedback mechanisms, when measured in information units, is relatively constant over a considerable ...

predicting ebay's online auction prices using functional data analysis

you can also fit a curve = polynomial fitting

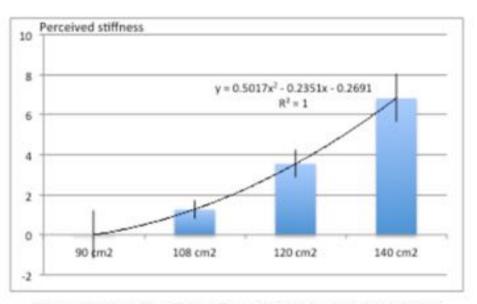

Figure 11. Bradley-Terry-Luce model output as well as a polynomial regression.

Our results are illustrated in Figure 11. We observed a clear distinction between the perceived stiffness of the 4 patches, the size of the patch increasing the perceived stiffness. In particular A is the least restrictive, followed by B, then C and then D is the most restrictive. We found that each paired comparison was significant (p<0.0125). This thus allows us to compare the different patches and conclude that D is the most efficient patch. We also performed a polynomial regression on our data and found a very accurate fit: y=0.5017x2-0.2351x-0.2691 (R²=1). This suggests a quadratic correlation between the area of the patch and the perceived stiffness, which allows us to imagine bigger patches in order to restrict movements of the knee, which would require more stiffness. Of course further investigations need to be done to confirm this.

The following table shows general guidelines for choosing a statistical analysis. We emphasize that these are general guidelines and should not be construed as hard and fast rules. Usually your data could be analysis. choose among them based on the number of dependent variables (sometimes referred to as outcome variables), the nature of your independent variables (sometimes referred to as predictors). You also want to consider many distributed (see what is the difference between categorics, ordinal and interval variables) for more information on this). The table then shows one or more statistical tests commonly used given these types of Number of Dependent Variables Nature of Independent Variables Nature of Decembers Variables (Texto) How to SAS How to State How to SPSS How to R D Ms B population Interval & normal one sample t-test ordinal or Intervel one-sample median categorical (2 categories) salegorical Chi-square goodness of fit 1 fV with 2 levels (independent groups) Interval & revenue 2 independent sample t-test 5255 ontinal or interval Whiceson March Whitney Sest categorical Chi-square test Figher's exact test 5255 What type of data? discrete independent with 2 or more levers (independent groups) interval & normal one-way ANOVA 5255 independent variable ordinal or interval Kruskel Wells 5255 200t Continuous Discrete/categor dependent ical dependent dependent categorical Chi-square test 5255 variable variable variable variable with 2 levels (dependent/matched groups) Intervel & normal period Front 2 grp >2 grp logistic regressions ordinal or interval Wilcoxon signed ranks test State Non paired diregorical McNeme >2 grp >2 grp 2 grp with 2 or more levels (dependent/matched groups) interval & normal one-way repeated measures ANOVA Counts >= 5 in >= 75% Non paired Non paired Counts >= 5 in ordinal or interval Friedman test 5P95 campoorical (2 campoories) repeated measures logistic regression SAS 5P55 more Ns (independent groups) interval & normal factorial ANOVA 5255 ordinal or interval ordered logistic regression State SP\$5 categorical (2 categories) factorial logistic regression interval & normal State interval & normal simple thear regression. ontinet or intervel non-parametric correlation \$255 simple logistic regression Lor more Interval IVs and/or Lor more categorical IVs.
